Native IP Stack For Zephyr™ OS
Why a native IP stack?

• Features missing in current Contiki based uIP stack
  • No dual IPv6 & IPv4 stack
  • Only one bearer (BLE / 802.15.4) usable at a time
  • One adapter only (like no 2 x 802.15.4 device)
  • Memory management issues (too big buffers for small amount of networking data)
  • Difficult to adapt uIP to multithreaded Zephyr OS

• Automatic testing of the network stack
Why not port 3rd party IP stack?

- Use native stack instead of embedding existing stack like lwip or FNET
  > avoid adaptation layers which cause overhead
  > use same network buffers everywhere to utilize memory efficiently
  > unified look and feel of the APIs and code (helps maintenance)
  > creating testing harness easier with new stack
How to do it?

- Re-write IPv6 and IPv4 components to enable dual stack
- Avoid any adaptation layers by utilizing Zephyr OS services directly
- Utilize memory better by enabling IP stack to use smaller buffers that can be linked together
- Creating a testing framework to test the stack automatically
Key Features

- Native dual IPv6 and IPv4 stack
- Built around network buffer pools concept, efficient memory management
- Possibility to have Zero/minimal copy data path from user space to device driver
- Supports Thread IP requirements
- Native KConfig integration
- Uses automated testing harness for running network stack tests

One RX fiber
- Global RX FIFO for receiving
- array of network contexts ("sockets")
- Look up Tasks’ Rx FIFOs

Multiple TX fibers
- Each network device has its own TX fiber
- Write to device drivers TX FIFO

RX fiber
TX fiber, one per interface
RX FIFO
TX FIFO
Network interface
Network interface

Task A
Task B
Key L2 features

- Dedicated OSI L2 abstraction
- Supports multiple bearers and interfaces such as IEEE 802.15.4 and Bluetooth*
- Concurrent TX/RX on all interfaces
- Spec-compliant 802.15.4 implementation
- Supports current Zephyr OS network drivers with small modification

*Other names and brands may be claimed as the property of others.
Automatic Testing

• Component tests created that will test some specific part of the networking stack (example: 6lo, neighbor mgmt, ip-addr mgmt etc.)
• These tests are executed automatically for each commit
• Full network stack conformance testing run periodically
Network buffer overview

- `net_buf`'s can be chained together to allow sending or receiving bigger amount of data
- Amount of fragments is configurable by Kconfig option
- Size of the network data part of the fragment can be configured via Kconfig
- User specific data part in the first fragment can contain protocol specific information
- Example: typical size of the network data part is 128 bytes for 802.15.4
Network buffer details

- Link layer header pre-allocated in the net_buf
- Requires application data partitioning when sending the data
- When receiving, the application needs to read the data in chunks as the data is not continuous
- The L2 layer will insert link layer data to the start of the net_buf
Release Plan

• Currently native IP stack code under development can be found at “net” branch in Zephyr OS git [1]
• Merge native IP stack to Zephyr OS 1.7 release
