  - OSS Monitoring Software Developer
  - CI Developer
Summary

- Live patch explanation
- Current live patch services
  - Motivation for elivepatch
- Elivepatch solution
  - Implementation
  - Challenge
  - Status
  - Future Work
- Conclusion
At first this project was part of Google Summer of Code 2017 for the Gentoo organization.
Live patch explanation
Live patch

Modify the kernel without the need to reboot.
Why

- Downtime is expensive (containers, supercomputers)
- Security (vulnerability time shorter)
Where

- Embedded
- Desktops
- HPC (complex scientific computations)
- Cloud
- Any computer under heavy load
What

- Kpatch
- Livepatch
- Kgraft
Kgraft

Suse Open Source live patching system that is routing the old function gradually.
Kpatch

Red Hat Open Source live patching system and use ftrace and stop_machine() for route functions toward the new function version.
Livepatch

Livepatch is a hybrid of kpatch and kgraft. Livepatch has been merged into the kernel upstream.

Kpatch-build can work with both kpatch and livepatch for creating the live patch.
Livepatch is just a module
Livepatch module problem

A module that takes just about 1+ hour to compile in a modern server
At Gentoo, we know what means to compile something for more than 1 hour…
Gentoo solution to compile for 1+ hour compilation problem

- Gentoo “binary host”
- Pre-compiled binary
What options do we have for compiling livepatch modules?
Current existing livepatch services
Current vendor solutions

- Oracle, Ksplice (support only Oracle Linux kernels)
- Suse Linux Enterprise Live Patching (support only Suse Kernels for one year)
- Canonical Live Patch (support only Ubuntu 16.04 LTS and Ubuntu 14.04 LTS)
- Red Hat live patch (Support only Red Hat kernel)
Motivation for elivepatch
Problems of vendor solutions

- trusting on third-party vendors
- Lacking support for custom kernel configurations
- Lacking support for request-driven customization
- Lacking long term support
- Closed source
elivepatch solution
elivepatch
A web service framework to deliver Linux kernel live patches

- Supports *custom kernel configurations*
- User participation via *request-driven* customization
- *Open source*
Vendor solutions representation

Client

Loadable Patch Module

Third Party Live Patch Server
Elivepatch solution

Elivepatch Client

```
{
  "Request Payload": {
    "Kernel Version": "4.14.16",
    "Kernel Configuration": "/tmp/kernel.conf",
    "Patch": {
      "Main patch": "/tmp/main.patch",
      "Incremental patch": [
        "/tmp/elivepatch/0001.patch",
        "/tmp/elivepatch/0002.patch"
      ]
    }
  }
}
```

Loadable Patch Module

Live Patch Request

Elivepatch Server

Kpatch-build

RESTful API

REST
Implementation
Elivepatch-server (Main language: Python)  
Flask + Flask-Restful + Werkzeug (not dependent)  

Elivepatch-client (Main language: Python)  
Requests + GitPython
Challenges
Challenges with elivepatch

- Some patches require manual modification to be converted to live patches
- Reproducing the build environment can be difficult:
  - Differences in compiler versions
  - Variations in the compiler and optimization flags
- Incompatible machine architectures (solaris, hpc)
Incompatibility with GCC

CCFLAGS and non vanilla gcc, can sometime broke elivepatch.
Current status
Elivepatch status

- First open source release 0.1 on 2017/9/06
- Packaged for Gentoo
- **Kpatch version 0.6.2 in Gentoo**
- Presented as poster at SOSP 2017
- Close collaboration with kpatch maintainers
Future work
Future work

- Toward livepatch automatization
- Increasing scalability using containers and virtual machines
- Livepatch signing
- Kernel CI\CD check
Toward livepatch automatization

- Priority is to automatize the livepatch creation when there are no semantic changes. For example, we need to detect inlined functions and optimizations that require including more functions into the livepatch.
- Need a tool for creating the extra relocations entries.
Linux Plumbers 2018

- Architecture support
  - objtool for ppc (**Miroslav Benes, Kamalesh Babulal, Josh Poimboeuf**)
  - s390x (**Joe Lawrence, Miroslav Benes**)
- Dealing with gcc optimizations interfering with livepatches (**Miroslav Benes**)
- userspace tooling for automating patch generation (**Alice Ferrazzi, Miroslav Benes, Nicolai Stange**)
- elivepatch presentation / discussion (**Alice Ferrazzi**)
- How to implement a sane notion of global consistency (**Nicolai Stange**)
- compatibility of livepatches between framework versions (**Joe Lawrence, Petr Mladek, Nicolai Stange**)
- general experience sharing after 1+ years of livepatching being [commercially] supported in distributions (**Josh Poimboeuf, Jiri Kosina, ... ?**)
Multi distribution

Solve distributions compatibility issues

Current target:

- Debian
- Fedora
- Gentoo
- Android
Elivepatch client on Debian

Work in progress…

https://asciinema.org/a/187738

p.s. Gentoo kernel is still needed
Livepatch signing

- Implementing livepatch module signing in the server
- Implementing signing verification for the client
Kernel CI/CD checking

- Implement a buildbot plugin for testing elivepatch
- Implementing elivepatch-server on docker, for a ready to use livepatch building instance

[You can test your livepatch with the same settings and hardware as where you want to deploy it]
Conclusion
Epilogue

- Live patch is a module that takes time compiling
- Live patch vendor service solutions solving the compilation problem
- Elivepatch solution
With the diffusion of embedded systems and robotics,
Livepatch services will become always more important
If you are interested in contributing, Elivepatch is welcoming every form of contribution.
