Problem definition

Product life cycle: more than 10 years

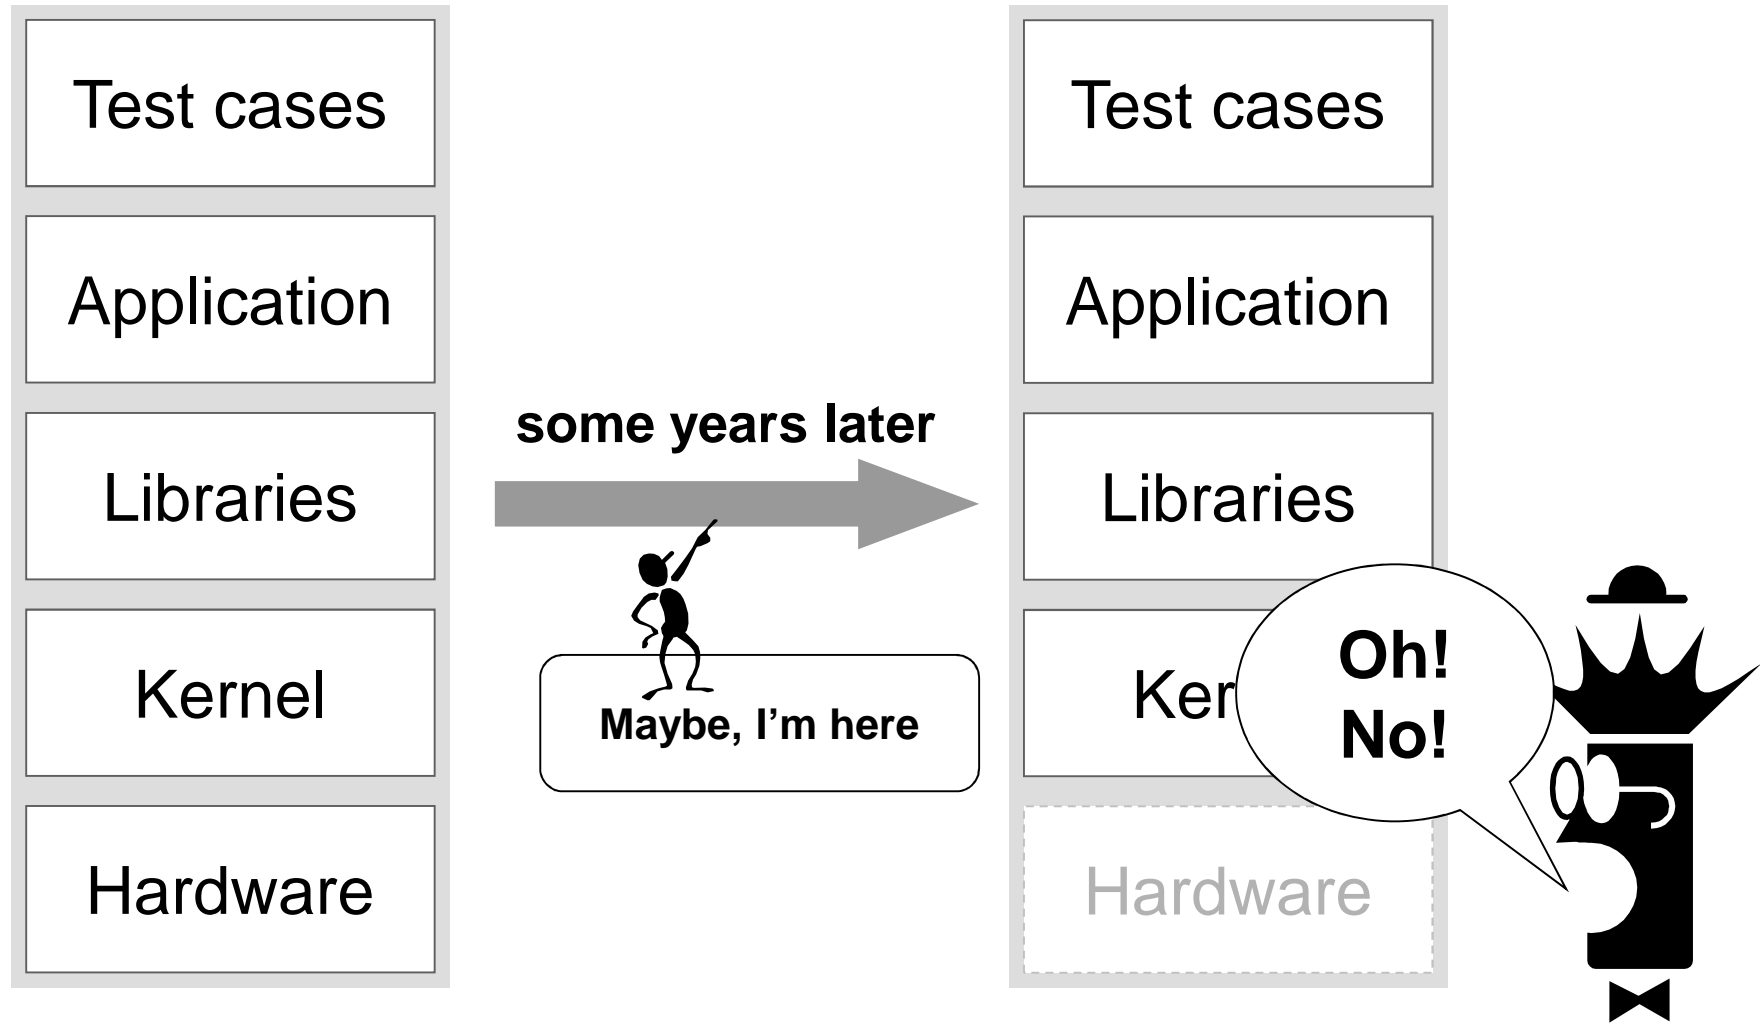

Problem definition

Product life cycle: more than 10 years

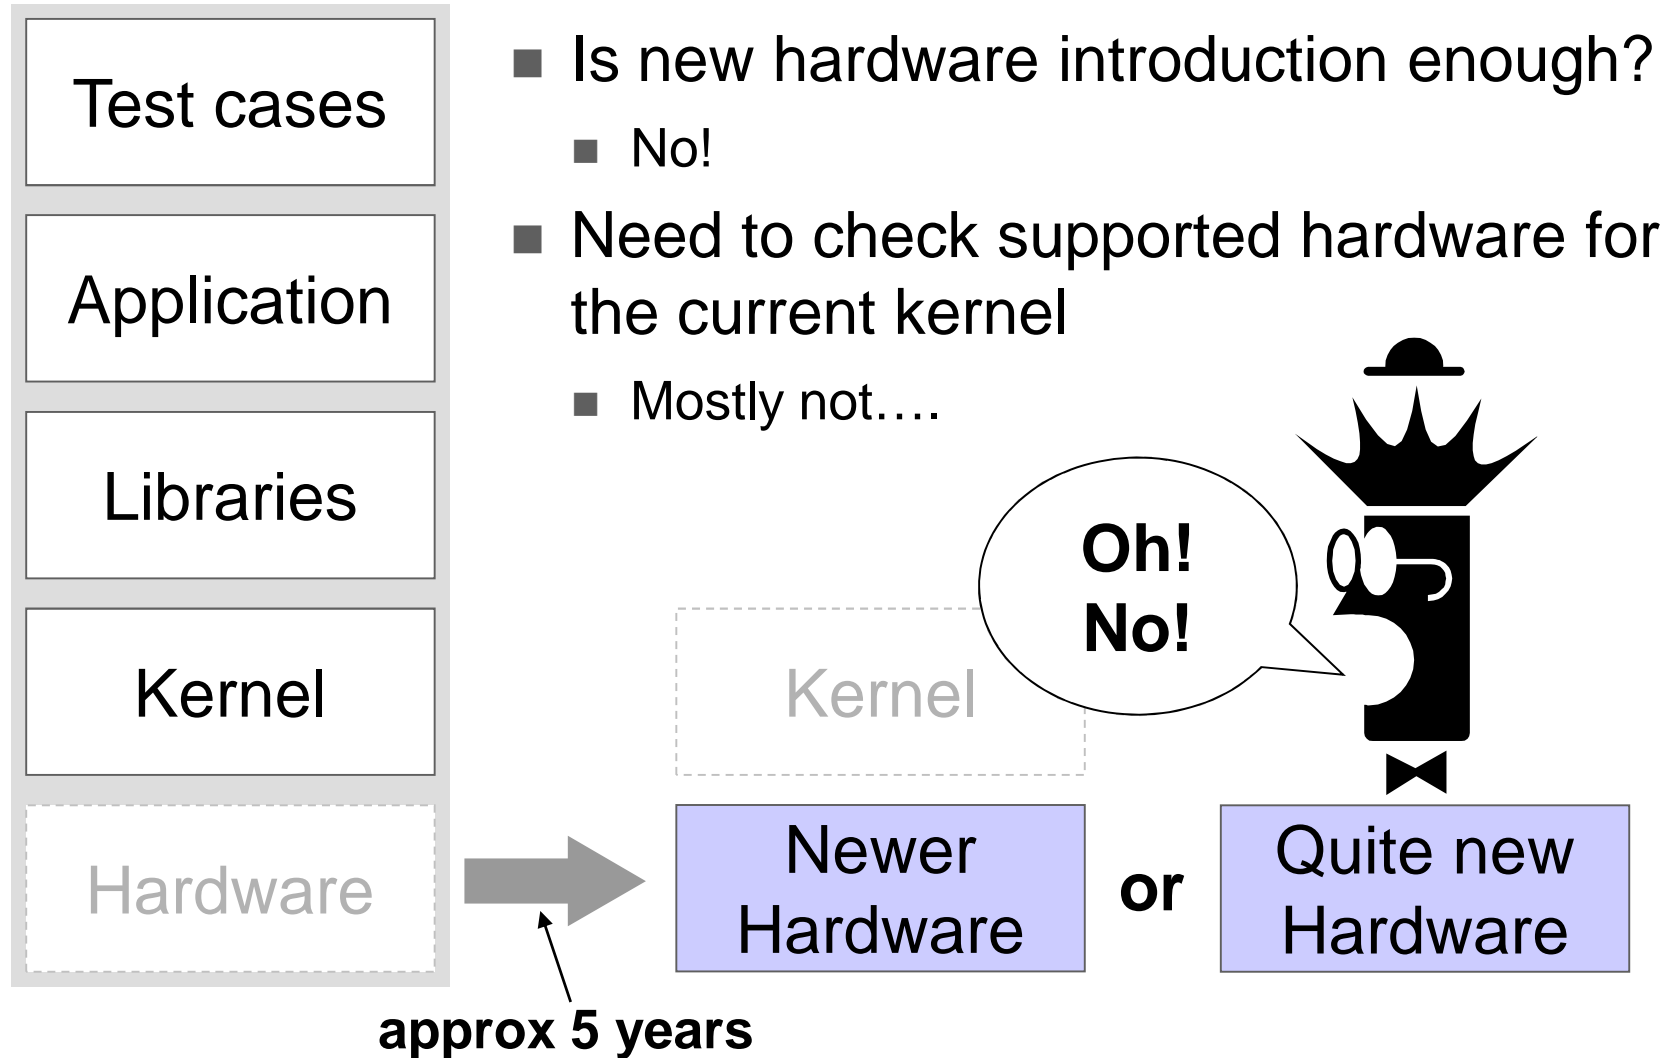

Problem definition

Product life cycle: more than 10 years

Problem definition

To overcome the hardware discontinuation:

Question 1: How to adapt the new hardware

- Which approach is the better?
 - Upstream kernel driver backports on the old kernel
 - Change the current product's kernel to newer one

Question 1: How to adapt the new hardware

- Which approach is the better?
 - Upstream kernel driver backports on the old kernel
 - Change the current product's kernel to newer one

- The answer is ...
 - I'm not sure

- The correct answer depends on:
 - Hardware specification
 - User's (or Programmer's) requirement

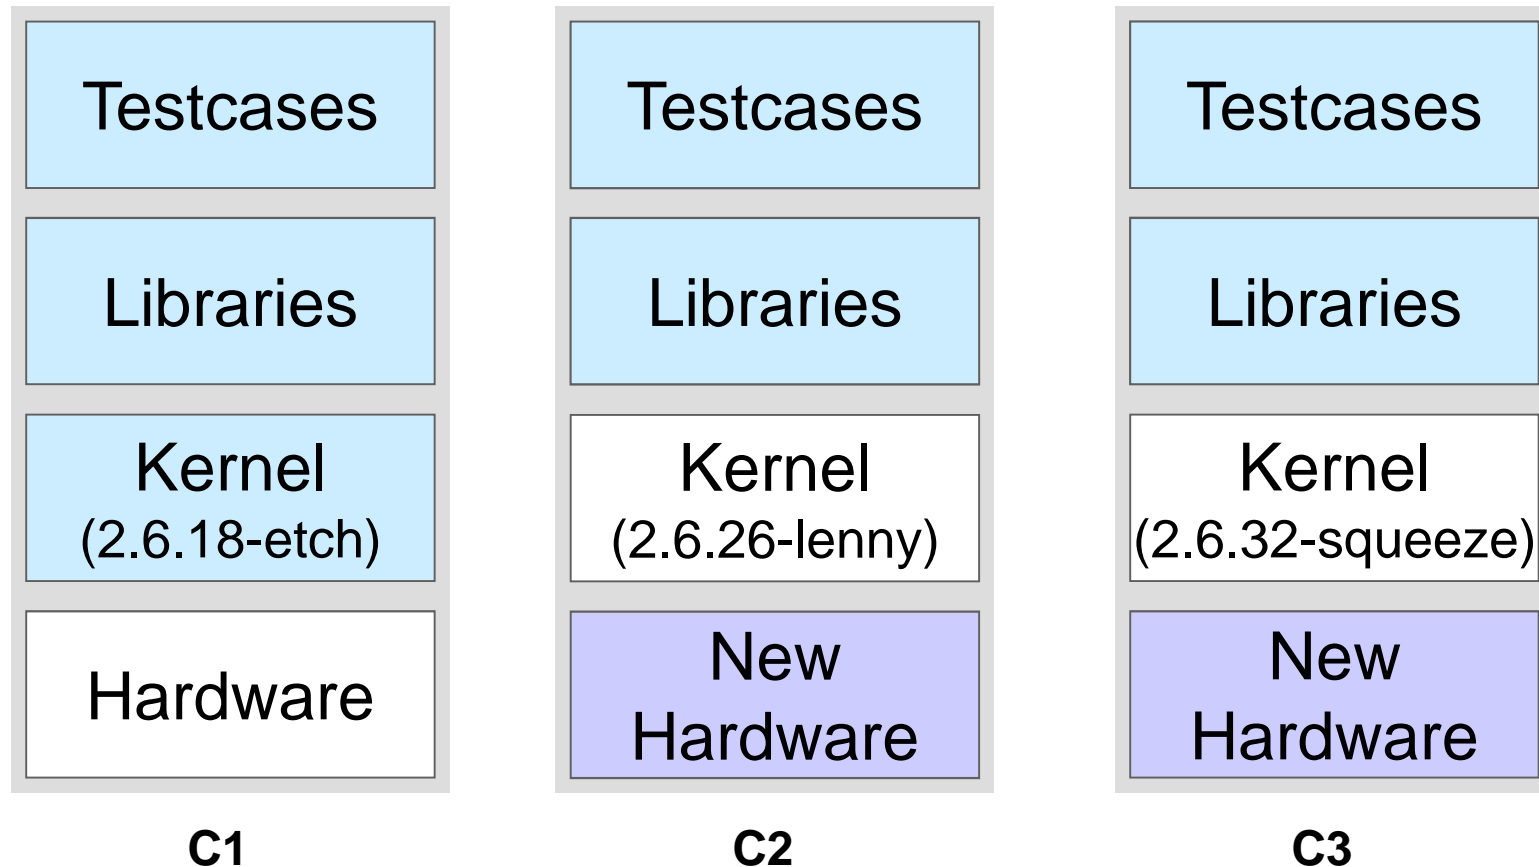

- In this BoF, think about use newer kernel version to move forward

Question 2: Required tests

- What kind of test do I need to do to make sure the compatibility?

Case study 1: API level tests

- Test environment
 - Same libraries and testcases are used on each kernel version

LTP results

- C1: 2.6.18-etch + Etch environment
 - Error count that failed only on new hardware: 1
 - cron02
 - Note: This kernel doesn't fully support new hardware
- C2: 2.6.26-lenny + Etch environment
 - Error count that failed only on new hardware: 3
 - getcpu01, stime01, cron02
 - needs to run separately: mtest06, cron_deny01
 - Note: This kernel supports almost all devices on new hardware
- C3: 2.6.32-squeeze + Ethc environment
 - Error count that failed only on new hardware: 7
 - execve04, getcpu01, swapon03, sched_cli_serv, clock_gettime03, timer_create04
 - Note: This kernel supports almost all devices on new hardware

Determine the reason for the errors on 2.6.26

- getcpu01
 - Only runs >2.6.20
 - Need NUMA support
- stime01
 - time() returns stime()-1
 - A bug fix is available on 2.6.27.13
 - Easy to fix

Case study 2: Performance verification

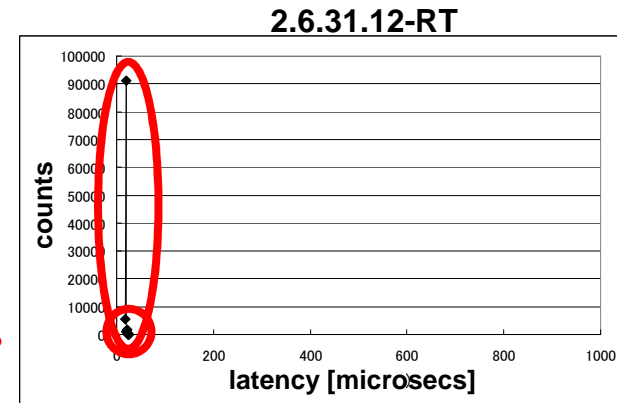

- CPU performance
 - Has to be better than old one if the application's CPU usage is high
 - This is easy to fix
- Network throughput
- I/O throughput

- The following aspects are important for real-time systems
 - Scheduling latency
 - Network latency
 - ...(any others?)

Latency test (cycle 300μs / cpu and memory load)

CPU load

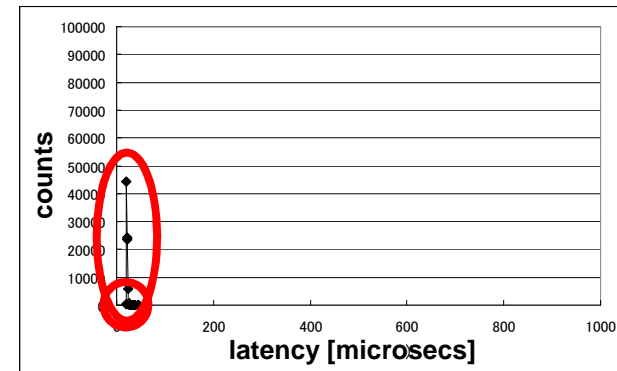

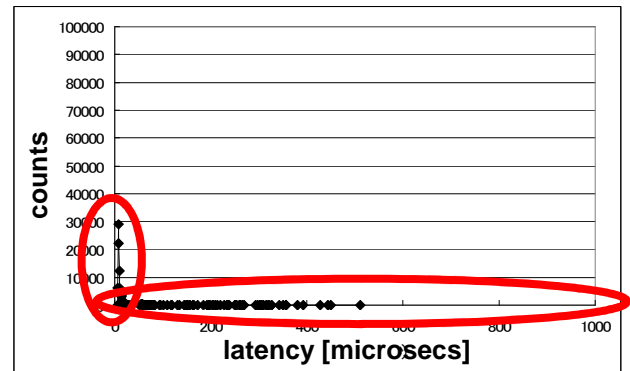

0 %

50 %

100 %

Latency test(cycle 300μs / CPU load only)

CPU負荷

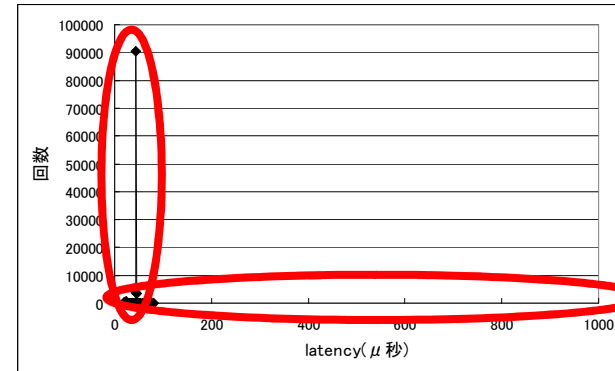

0 %

50 %

100 %

Why this happens?

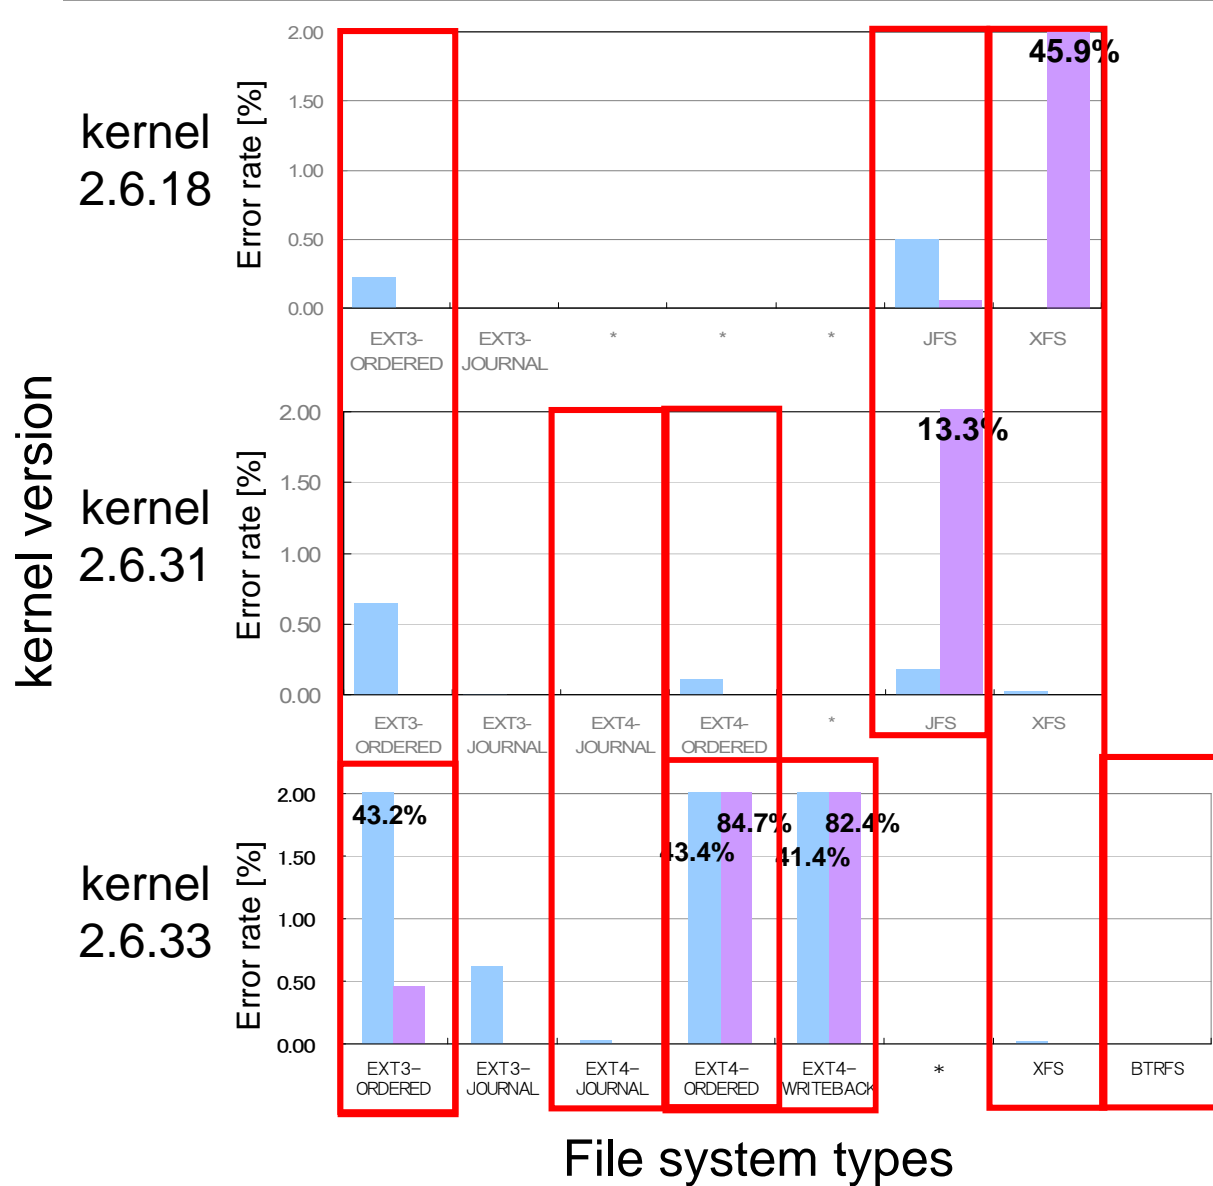

- **Probably** hardware problem
 - Try to find the bottlenecks by ftrace
 - This latency problem randomly happens in the kernel
 - If same test runs on other machines, nothing happened
- In this case, just throw away the hardware
 - or ask customer service

Case study 3: Quality verification

- Quality verification for:
 - File systems
 - Long-term running

Results of data reliability tests

■ File size mismatch rate
■ Data mismatch rate

Point 1:
An filesystem has different characteristics on different kernel

Point 2:
2.6.33 has high error rate on ordered and writeback mode

Point 3:
Ext4-journal and Btrfs has good results

Conclusion

- This BoF discussed what kind of tests are required to follow newer kernel version
 - The following aspects are only examples
 - API level compatibility
 - Performance compatibility
 - Service quality compatibility

- Of course, application specific tests has to run
